ACKNOWLEDGMENTS

This manuscript was prepared for publication by B. R. Ferguson and P. S. Young. The authors express their appreciation for the fine quality of the manuscript as well as their cheerful assistance in performing the many tasks associated with publication.

The brief duration and successful completion of this study were made possible by a high level of cooperation on the part of several individuals and organizations. Staff members of the Babcock and Wilcox Company supplied information on the as-built reactor core, the zero-power startup benchmark critical configuration and the core damage assessment.

G. T. Mays of the Nuclear Safety Information Center, ORNL, assisted in the acquisition of information from the Final Safety Analysis Report.

D. O. Campbell of the Chemical Technology Division, ORNL, supplied information on the soluble boron content of the damaged reactor. R. E. Pawel of the Metals and Ceramics Division, ORNL, discussed the zirconium oxidation reaction and its implications for potential core damage.

L. M. Patrie and N. F. Landers of the Computer Sciences Division, UCCND, developed the MAKARAY KENO-IV input-processing program on an urgent basis. Priority was given to the machine computations by the operations staff of the computing facilities at the Idaho National Engineering Laboratory and the Oak Ridge National Laboratory. Finally, the highly sophisticated analytical capabilities used in this study were developed under continuing programs supported by the Office of Nuclear Material Safety and Safeguards and the Office of Nuclear Regulatory Research, U. S. Nuclear Regulatory Commission.

**CRITICALITY ANALYSES OF DISRUPTED CORE MODELS
OF THREE MILE ISLAND UNIT 2**

R. M. Westfall, J. T. West, G. E. Whitesides, and J. T. Thomas

ABSTRACT

Three hypothetical disrupted core models were analyzed for the President's Commission on the Accident at Three Mile Island. Soluble boron in the present configuration was assumed to be 3180 weight parts per million (wppm). Positive reactivity effects due to fuel swelling, fuel slumping, and coolant displacement by ZrO₂ increase the cold, shutdown system multiplication factor from approximately 0.7^b to 0.86. The increase in reactivity for the three models can be roughly correlated with a decrease in the borated water-to-fuel volume ratio. Each of the 39,825 pin-lattice locations was modeled explicitly in the Monte Carlo analyses of the reactor core. Parametric studies were performed with one-dimensional discrete-ordinates analyses. The report includes a benchmark critical analysis of the system at hot, zero-power startup, a description of the analytical methods used, and a comprehensive compilation of the data upon which the analytical models were based.

I. INTRODUCTION

At the request of W. R. Stratton, staff member of the President's Commission on the Accident at Three Mile Island, a series of analyses were performed to determine the reactivity effects of various hypothetical modes in which the reactor core of Three Mile Island Unit 2 may have been disrupted. The results of these analyses were forwarded to Dr. Stratton for use in preparing his portion of the commission report. The purpose of this memorandum is to provide formal documentation of this effort in terms of the hypothetical models studied and the analytical methods applied. The scope of this study was restricted to the disrupted core analyses. No quantitative judgment was made as to the likelihood of

the occurrence of the particular accident modes. Also, no recommendations are made as to specific actions to be taken to avoid a criticality incident during plant recovery operations.

The sources of information used in constructing the disrupted core models are described in Section II. This information includes data on the reactor design, a benchmark critical configuration, possible core disruptive mechanisms, and the soluble boron content of the reactor coolant. The disrupted-core models are described in Section III. The analytical methods are described in Section IV. This section includes a brief description of the 27-group neutron cross-section library and the geometry modeling features of the Monte Carlo transport programs MORSE-SGC/S¹ and KENO-IV.² The capability of these programs to represent the disrupted core with a high level of geometric detail was the primary reason for performing this study at Oak Ridge.

The results of the study are presented in Section V. The results pertain to three categories:

1. Parametric studies of the effects of fuel pin geometry changes determined through infinite-lattice pin-cell calculations.
2. A benchmark analysis of the as-measured critical configuration at hot, zero-power reactor-startup conditions.
3. Analyses of the disrupted core models including variations to determine the reactivity worths of the soluble boron, the control rods and the burnable poison rods.

Conclusions drawn from these results are summarized in Section VI.

II. MODEL DESIGN DATA

Reactor Design--The primary source of data on the design of Three Mile Island Unit 2 was the Final Safety Analysis Report (PSAR).³ Information was taken from this report on the following design features:

1. Fuel assembly design, compositions and dimensions including
 - a. fuel pins,
 - b. control rods,
 - c. axial power shaping rods,
 - d. lumped burnable poison rods,
 - e. orifice rods, and
 - f. instrumentation guide tubes.
2. Cycle one fuel-loading scheme.
3. Rod locations, 0-200 full power days.
4. Reactor vessel and internals.

Copies of the tables and figures from which this information was taken are included here as Appendix A. This information was supplemented with particular details supplied by the Babcock and Wilcox Company. These pertain to the various fuel enrichments, given in Table 1, the B₄C loadings of the lumped burnable poison rods, given in Table 2, and the density of the Ag-In-Cd control rods (10.17 g/cc). All analyses in this study include fuel and fixed-absorber compositions based upon the beginning-of-life value. That is, no variation due to the brief operating history of the reactor was taken into account.

LPB-3	1.060

^a Al₂O₃-B₄C mixture at 3.7 g/cc.

^b Natural boron.

Benchmark Critical--Additional information supplied by the Babcock and Wilcox Company included a set of conditions under which Three Mile Island Unit 2 was critical.

1. Hot, zero-power startup (fuel and moderator at 551°K).
2. Coolant at 2200 psi (0.77 g/cc).
3. Soluble boron at 1490 wppm.
4. Control rods out.
5. Axial power shaping rods out.

Core Disruptive Mechanisms--Information concerning the possible modes in which the reactor core may have been disrupted was provided by staff members of the Babcock and Wilcox Company and by cognizant individuals at Oak Ridge National Laboratory. Three major phenomena have been postulated.

1. Zirconium Oxidation

- a. function of temperature and steam distributions.
- b. hydrogen release indicated approximately 35% of Zircaloy oxidized.
- c. ZrO₂ probably flaked off and crumbled.
- d. damage concentrated in upper axial center of core.
- e. damage likely on fuel rod clad, possible on LBP rod clad and control rod guide tubes.

2. Fuel Swelling

- a. rapid depressurization of core may have caused clad to "balloon out" and rupture.

- b. thermal stresses may have caused UO₂ to crack and crumble.
- c. UO₂ may convert to U₃O₈ at a lower density (10.96 vs 8.3 g/cc theoretical).

3. Fuel Slumping

- a. may occur with loss of clad integrity and physical displacement of UO₂.
- b. heat transfer analyses indicate that the melting point of UO₂ may have been exceeded in the top central portion of the core.
- c. severe downward displacement of the fuel believed to be restricted to the area above the third axial spacer grid at the center of the core extending radially and upward to the first axial spacer grid at the third fuel assembly from the edge of the core.

Soluble Boron Content--Coolant samples dated June 7, 1979, and analyzed at Oak Ridge National Laboratory contained a boron content equivalent to 2400 wppm. Trace amounts of silver, indium, and cadmium were detected. The boron content was scheduled to be increased to 3180 wppm by July 1, 1979.

III. DISRUPTED CORE MODELS

Three disrupted core models were analyzed. For the intact portions of the reactor core, each of the three models included an explicit representation of the contents of the 39,825 pin lattice locations. That is, the fuel rods, control rods, axial power shaping rods, lumped burnable poison rods and the orifice rods were each treated with all available detail as to composition and geometry. No distinction was made between the 40 instrumentation tubes containing in-core detectors and the 137 remaining water-filled locations. Staff members of the Babcock and Wilcox Company have indicated that the in-core detectors are worth about 0.2% Δk/k in negative reactivity. The major difference between the three disrupted core models was in the number of axial layers used to represent the disrupted portion of the core. The MORSE-SGC/S model includes seven

axial levels in the core while the KENO-IV models have a maximum of two axial core zones.

MORSE-SGC/S "Three Jump Slump" Model--This disrupted core model is shown in Fig. 1. The intent in designing this model was to incorporate all of the core disruptive mechanisms in an internally consistent manner. Thus, all of the fuel pins in the core are swollen by 30 percent with the fuel consisting of a $\text{UO}_2\text{-U}_3\text{O}_8$ mixture with effective densities calculated to fill the increased volume and conserve the original mass of uranium. The densities for the two components in this mixture were 6.521 g/cc for U_3O_8 and 1.534 g/cc for UO_2 . Complete conversion from UO_2 to U_3O_8 (at a constant percentage of theoretical density) would result in a volume increase of 37 percent.

A second major feature of this model concerns the disposition of the ZrO_2 formed in the upper central portion of the core. Here it is assumed to be uniformly distributed in the coolant channels immediately below the slumped fuel. The ZrO_2 occupies 32.9 percent of the flow channel areas for an axial distance equal to the length of the slumped fuel. The fuel element spacer grids would be the primary mechanism for preventing the ZrO_2 from exiting the core.

The third major feature of this model concerns the nature of the slumped fuel. With the loss of the zircaloy clad, it is assumed that the UO_2 converts to U_3O_8 and is physically displaced downward to rest upon the spacer grids and non-disrupted fuel. The fuel is assumed to be a mixture of the types A and B fuel assemblies located in the disrupted region yielding an average enrichment of 2.3 wt % U-235. The slumped fuel has a 0.687 volume factor which is near the theoretical maximum

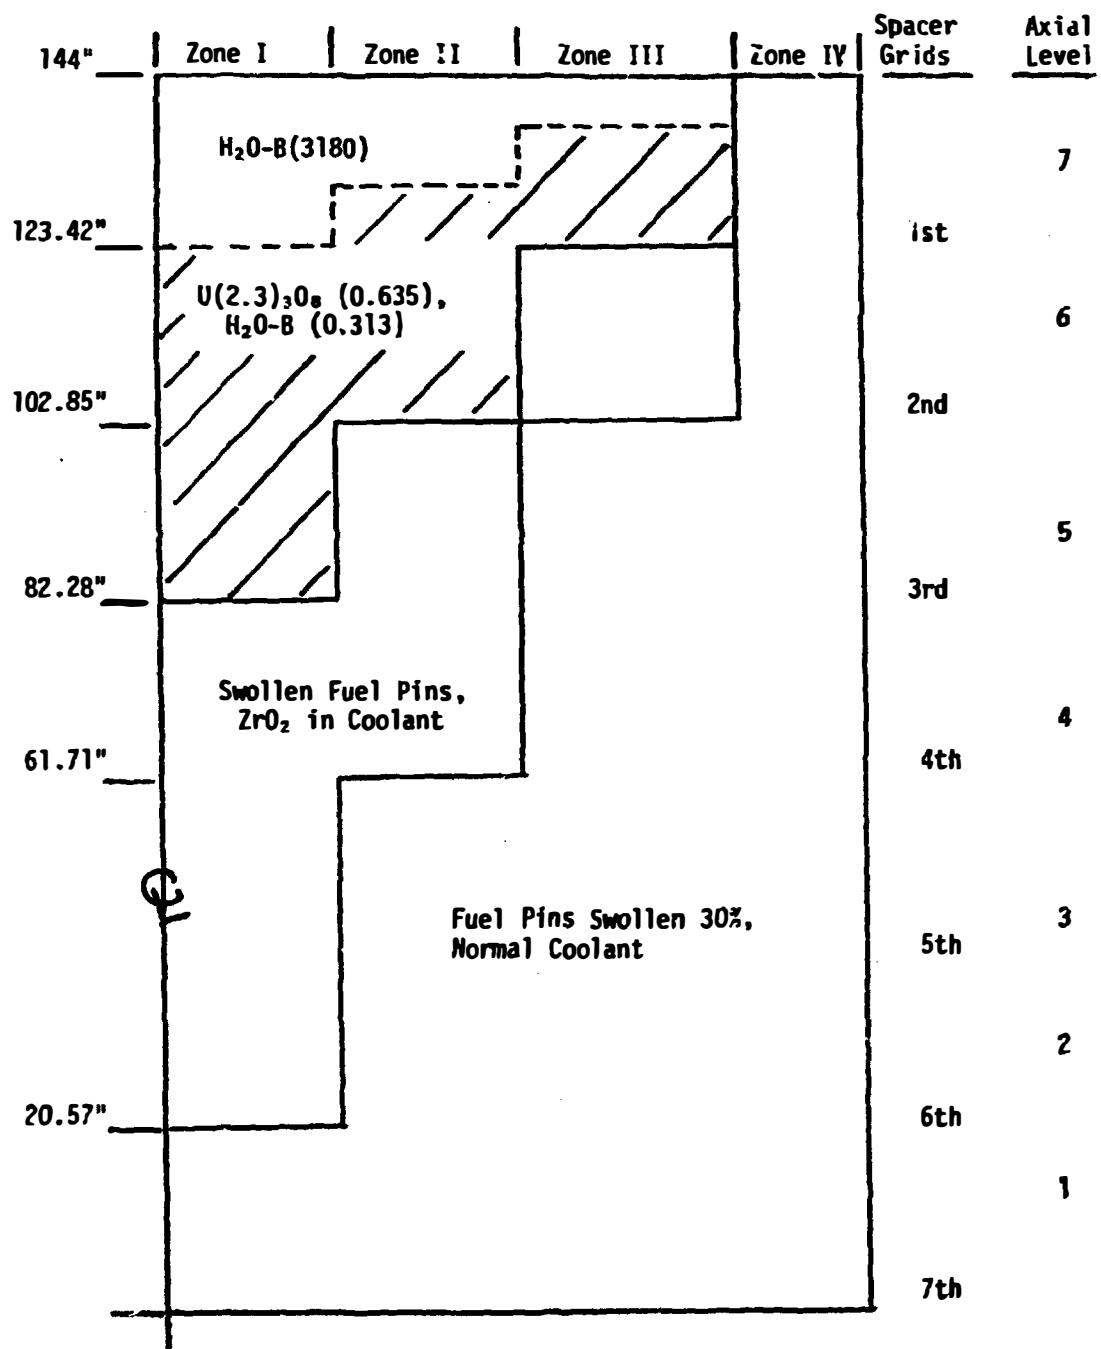

Fig. 1. MORSE-SGC/S Three Jump Slump Core Model*

*Control and Lumped Burnable Poison Rods from Disrupted Portion of Core Missing. Boron in Coolant in All Zones at 3180 wppm. Core Barrel, Radial, and Axial Reflector Regions in Model.

packing factor for spheres. The U₃O₈ and borated water are the only materials remaining in the disrupted region of the core. That is, portions of the control rods, lumped burnable poison rods and orifice rods that originally extended through this region have been removed from the model. This is a conservative assumption from the criticality safety point of view.

There are four radial zones in this model. A detailed layout of the contents of each radial zone is given in Appendix B. This appendix includes a description of how this model was mocked-up using the array of arrays feature of the MORSE-SGC/S geometry package. Of particular interest is the manner in which the overall pin lattice array was truncated axially and indented radially to accommodate the representation of the disrupted portion of the core.

KENO-IV "Displaced-Fuel Slump" Model--This disrupted core model is shown in Fig. 2. Here it is assumed that the complete upper half of the core has been disrupted. The fuel has converted to U₃O₈ and been displaced downward to form the same U₃O₈-H₂O + B mixture assumed in the MORSE-SGC/S model. However, the fuel enrichment used here was 2.57 wt % U-235, which corresponds to the core average. This model assumes that the fuel clad and the other non-fuel materials in the disrupted region have been removed from the core. The lower half of the core is the normal pin lattice configuration (39,825 lattice locations). Details of the geometry mock-up in KENO-IV are given in Appendix C.

KENO-IV "In-Place Fuel Slump" Model--This disrupted core model is shown in Fig. 3. Here it is assumed that the fuel pin expands radially at constant clad density and volume and that the UO₂ slumps axially at

constant density and volume. Including the as-built core, five fuel heights were analyzed. The minimum fuel height corresponds to the case in which the outer diameter of the fuel pins is equal to the lattice pitch (1.443 cm) and thus the fuel pins are touching. The three intermediate fuel heights correspond to 25, 50, and 75 percent of the total possible increase in the cross sectional area of the fuel. The fuel pin clad and the other nonfuel material above the active portion of the core are present in this model. Details of the geometry mock-up in KENO-IV are given in Appendix C.

IV. ANALYTICAL METHODS

Neutron Cross Sections--The neutron cross sections used in these analyses were taken from a 27 energy-group library developed from ENDF/B-IV data for the U. S. Nuclear Regulatory Commission. The 27 energy-group structure was determined through an extensive series of model calculations.⁴ The group structure includes the boundaries of the 16-group Hansen-Roach⁵ cross-section library with two additional boundaries in the high-energy "fission-spectrum" range and nine additional boundaries in the low-energy "thermal-upscatter" range. The group structure is given in Table 3.

Resonance processing was performed using the NITAWL-S module of the SCALE system. This module applies the Nordheim⁶ method to calculate resonance self-shielding for the absorber materials located in a pin-lattice cell. Resonance processing was performed for nine nuclides: U-238, U-235, Zircaloy, Ag-107, Ag-109, In-113, In-115, Cd, and Mn. Several parameters determined the number of lattice-cell resonance analyses.

Table 3. 27-Broad-Energy Group Structure

Group No.	Upper Boundary	Group No.	Upper Boundary
1	20 MeV	15	3.05 eV
2	6.434	16	1.77
3	3	17	1.3
4	1.85	18	1.13
5	1.4	19	1
6	900KeV	20	0.8
7	400	21	0.4
8	'00	22	0.325
9	1'	23	0.225
10	3	24	0.1
11	55eV	25	0.05
12	100	26	0.03
13	30	27	0.01
14	10		0.00001

This group structure was found to be adequate through the broad-group-determination procedure for the nuclides: U-238, U-235, Pu-239, Pu-240, Pu-241, Pu-242, B-10, SS-304, (Ni, Fe, Cr), Cd, Al, Cu, H₂O, zircaloy-2.

1. Fuel enrichment
2. Fuel diameter and density
3. Fuel temperature
4. Temperature and density of the coolant
5. Boron content of coolant
6. Presence of ZrO_2 in coolant

Appropriate Dancoff factors for the various combinations of cell parameters were applied. The $U_3O_8-H_2O + B$ mixtures were treated as infinite homogeneous media in the resonance processing for U-235 and U-238. Fuel enrichment was the only variable in these analyses.

Of particular interest to this study is the expected performance of this cross-section library in the analysis of systems similar to Three Mile Island Unit 2. The results of previous analyses⁷ of pin-lattice critical experiments with ENDF/B-IV data are given in Table 4. The 27-group library is a subset of the 218-group library in the table. Also, the 19-group library is a subset of the 27-group library. Thus, the 27-group library would yield system multiplication factors consistent with the results from 218- and 19-group libraries. The results using point cross sections are in good agreement with the multigroup results. For comparison purposes, the lattice pitch for the Three Mile Island Unit 2 fuel assemblies is 0.57 inches and the effective water/fuel volume ratio is 1.27 for the hot, zero-power startup configuration. Thus, Cases 1, 2, and 5 correspond fairly well to the critical benchmark configuration for Three Mile Island Unit 2. From these results, the expected multiplication factor calculated with the 27-group library for the critical benchmark would be between 0.980 and 0.990.

MORSE-SGC/S--This is a new version of the MORSE¹⁰ Monte Carlo transport codes. It combines the supergroup capabilities of MORSE-SGC¹

^a468 vppm soluble boron

with a new array of arrays nesting feature developed for the U. S. Nuclear Regulatory Commission. The array of arrays feature provides for a single description of each type of fuel pin, lumped burnable poison rod, etc., followed by array specifications to define the fuel assemblies and a subsequent array specification of the fuel assemblies in the reactor core. The power of this procedure is demonstrated by the minimal computer storage requirement for the geometry description of the MORSE-SGC/S "Three Jump Slump" disrupted core model. Less than 9,000 decimal words of computer storage were required to describe the three-dimensional array containing 241,200 pin locations--plus the various uniform media bodies corresponding to the U_3O_8 - H_2O + B mixture and the water and steel reflector regions.

The MORSE-SGC/S analyses were performed on the Idaho National Engineering Laboratory CDC-7600 computer. Several initial neutron source distributions were specified for differing fuel regions. There was no discernable trend with source specification in the results. Standard variance reduction techniques such as Russian Roulette and splitting were applied. The analyses required about 1.2 minutes of CPU time per thousand histories calculated. Standard deviations of 0.003 were obtained with 60,000 histories, 0.006 with 30,000 histories, and 0.01 with 8,000 histories.

KENO-IV--This is the current production version of the KENO¹¹ series of multigroup Monte Carlo criticality programs. These programs feature an easily-specified geometry scheme which permits an extremely efficient particle tracking algorithm. The accuracy, efficiency, and ease-of-use of these programs has led to their being the most popular codes for

multidimensional criticality analyses. A high level of experience in this use has been accumulated in the last decade. Automated procedures in KENO-IV include source specifications, particle biasing, reflector weighting, and output edits.

The primary limitation in applying KENO-IV to this study stems from the very large number of pin-lattice locations that must be described. In KENO-IV, the entire mixed-box orientation array is stored in the computer memory. Thus, the primary application of KENO-IV has been to corroborate the MORSE-SCG/S results for those models requiring only one axial layer in the pin-lattice specifications.

Applying one-quarter core symmetry, the entire Three Mile Island Unit 2 reactor lattice was mocked-up in a 120 x 120 mixed box orientation array. A computer program, MAKARAY, was written to simplify the specification of this array. First the fuel assemblies were specified, then the combination of fuel assemblies corresponding to the first core loading was specified. From this information MAKARAY constructed the KENO-IV mixed-box orientation array for the one-quarter core. Note that the one-quarter core symmetry was achieved through the specification of hemicylinders for the pins lying on the I and Y core midplanes.

The KENO-IV analyses were performed on the Oak Ridge National Laboratory IBM-360/91 computer. The analyses required about 0.4 minutes of CPU time per thousand histories calculated. Standard deviations of 0.006 were obtained with 6,000 histories.

XSDRNPMS--This is the SCALE¹² system version of the XSDRN¹³ one-dimensional discrete-ordinates neutral particle transport programs. Its primary application in this study was in pin-lattice cell calculations

to determine the effects of various changes in fuel composition and geometry. The analyses were performed with the S₈ angular quadrature approximation and a P₃ scattering expansion order. ISDRNPM-S was executed in a SCALE system analytical sequence (CSAS1) which performs the problem-dependent cross-section processing and sets up the input for the transport analysis. MITAWL¹² input parameters and nuclide atom densities from these analyses were also used in the three-dimensional Monte Carlo analyses.

V. ANALYTICAL RESULTS

Infinite Pin Lattice Analyses--These analyses were performed to provide qualitative estimates of the reactivity effects due to possible core disruptive mechanisms. Since they are one-dimensional analyses, the combined effects of fuel and neutron absorbing rods are not calculated. Also, the neutron leakage is not taken into account. However, the leakage for this core is only worth about 4 percent in reactivity.

Generally, the reactivity effects are due to postulated changes in the fuel pin geometry and associated variations in the water-to-fuel volume ratio in the reactor core. One limit to this variation is the case of an infinite medium of U(2.96)O₂. The multiplication factor for this dry fuel case is 0.663. Note that the fuel enrichment corresponds to the highest of the three values for the Three Mile Island Unit 2 reactor core. Thus, some content of water and its associated neutron moderation must be present for this system to become critical.

The effects of water content on reactivity are complicated by the high soluble boron content of the reactor coolant. Pressurized water reactor fuel is normally considered to be undermoderated, that is, at

less than an optimum water-to-fuel volume ratio for maximum reactivity. Such is the case for the "cold clean" (unborated water) results listed in Table 5 and shown in Fig. 4. Reducing the lattice pitch lowers the multiplication factor still further. However, for the "cold borated" situation, the opposite effect is observed. The most reactive lattice pitch is significantly less than the design value. Eventually, the negative reactivity due to the loss of water overtakes the positive reactivity due to the loss of boron and the system multiplication factor comes back down.

The results of fuel swelling listed in Table 6 and shown in Fig. 5 reflect a similar variation. Fuel swelling removes water and boron from the system and the multiplication factor rises. Here the water-to-fuel volume ratio ranges from 1.65 to 1.07 while the lattice pitch variation discussed above resulted in a much wider range in this ratio (2.97 to 0.57). This limited range accounts for the monotonic behavior of the curves in Fig. 5.

The effect of boron concentration upon the system multiplication factor is given in Table 7. From 0 to 2400 wppm the reactivity worth of the boron is 1.13% $\Delta k/k_1 k_2$ per 100 wppm while from 2400 to 3180 wppm the worth is 1.08% $\Delta k/k_1 k_2$ per 100 ppm. Thus the incremental worth of the boron decreases as saturation is approached. These values are slightly higher than the 1% $\Delta k/k$ per 100 ppm soluble boron worth determined by the Babcock and Wilcox Company. This value, given in Table 4.3-11 of Appendix A, pertains to the hot reactor core at rated power. Thus the soluble boron worth should be somewhat reduced due to the lower water density and the presence of fixed absorbers.

2.64 wt % (Type B)	-	0.992	0.918	
1.98 wt % (Type A)	-	-	-	0.811

Table 8. Combined Fuel Swelling, Interstitial ZrO_2

Case	2.96 Wt % Enriched Fuel, Cell Description	Multiplication Factor
A	Normal fuel, boron at 3180 ppm	0.959
B	30% swollen fuel,* boron at 3180 ppm	0.992
C	Case B, 33 vol % ZrO_2 in H_2O	1.012

*Fuel composed of U_3O_8 and UO_2 inside zircaloy clad.

The combined effect of fuel swelling and coolant displacement by ZrO_2 is given by the data in Table 8. The overall effect is worth 5.5% $\Delta k/k_1k_2$ while the swelling alone is worth 3.5% $\Delta k/k_1k_2$.

The results in Table 9 demonstrate the relative worths of the Ag-In-Cd control rods and the $B_4C-Al_2O_3$ lumped burnable poison rods. In these analyses, the cell lattice pitch was taken as the average spacing between control rod centers, and the intervening fuel rods were treated as a homogeneous fuel-clad-coolant medium. The primary purpose of the analyses was to determine the input parameters for treating resonance absorption in the control rods. The results indicate that the control rods are worth substantially more than the lumped burnable poison rods.

The results of infinite medium calculations for the $U_3O_8-H_2O + B$ mixtures appearing in the MORSE-SCC/S "Three Jump Slump" model and the KENO-IV "Displaced-Fuel Slump" model are given in Table 10. Of particular interest is a comparison between the multiplication factor for the 2.57 wt % enriched fuel case with the corresponding pin cell result in Table 7. In going from the pin cell to the displaced fuel, the water-to-fuel volume ratio has gone from 1.65 to 0.46. The corresponding reactivity increase was 8.2% $\Delta k/k_1k_2$.

Benchmark Critical Analyses--The results of these analyses are given in Table 11. Good agreement is shown between the system multiplication factors calculated with MORSE-SCC/S and KENO-IV. Furthermore, these values are consistent with the 27 group results from the analyses of critical experiments having the same level of neutron moderation. Since the water density is 0.77 g/cc for this system, the effective water-to-fuel volume ratio drops from 1.65 to 1.27. Good agreement is shown between the results of Table 11 and the appropriate values in Table 4.

Table 9. Relative Rod Worths--
Control Rod vs LBP1

Absorber Type	Multiplication Factor
Ag-In-Cd rod, SS304 clad	0.466
LBP1-B ₄ C-Al ₂ O ₃ rod, Zr clad	0.680

*Pin-cell models include ZrO₂ and B(3180) in coolant, smeared U(2.57)O₂ fuel-clad-coolant.

Table 10. U₃O₈-H₂O^a Worth vs Enrichment

Fuel Enrichment	Multiplication Factor
2.3 wt %, inner core	0.948
2.57 wt %, core average	0.980 ^b

^aU₃O₈ at 68.7 vol % (0.635 theoretical density), H₂O and B (3180 wppm) at 31.3 vol %.

^bcf, U(2.57)O₂ K_m = 0.907 @ 3180 ppm boron,
see Table 7.

Comparison of Cases A and B of Table 11 yields the lumped burnable poison rod worth in this configuration to be approximately 5% $\Delta k/k_1 k_2$. This value is consistent with the 4.4% $\Delta k/k$ burnable poison rod assembly (BPRA) control worth listed in the (FSAR)³ and reproduced in Table 4.3-9 of Appendix A.

Comparison of Cases A and C yields the control rod worth in this configuration to be approximately 12% $\Delta k/k$. This value is consistent with the 10.5% $\Delta k/k$ control rod worth at hot zero power listed in the FSAR³ and given in Table 4.3-12 of Appendix A. The FSAR value does not include the worth of the axial power shaping rods shown in Bank 8 of Fig. 4.3-25 in Appendix A. Thus the FSAR value should be somewhat less than the value given by the present analysis.

Disrupted Core Analyses--The base case for these analyses is the normal core (nondisrupted) with the soluble boron level set at the 3180 wppm value corresponding to the current status. The results from analyses of this configuration are given in Table 12. Again, good agreement is seen between the MORSE-SGC/S and KENO-IV results. The control rods are worth approximately 9% $\Delta k/k_1 k_2$ and the lumped burnable poison rods are worth approximately 4% $\Delta k/k_1 k_2$. The high soluble boron level in the coolant tends to reduce the worth of the fixed absorbers.

The results from the analyses of the MORSE-SGC/S "Three Jump Slump" model are given in Table 13. Comparison of Case A with the as-built, cold shutdown case in Table 12 indicates that the overall positive reactivity worth of the disruptive core mechanisms is approximately 17% $\Delta k/k_1 k_2$. The water-to-fuel volume ratio in this core varies from 0.47 in

Table 11. Hot,^a Zero-Power Startup Configuration^b

Case Description	Monte Carlo Code	Multiplication Factor

B. Case A with LBP rods removed	MORSE-SGC/S	1.042 ± 0.011
C. Case A with control rods inserted ^d	MORSE-SGC/S KENO-IV	0.864 ± 0.008 0.863 ± 0.009

^aCoolant at 532°F, 2200 psi, $\rho = 0.77$, fuel at 532°F.^bControl rods out, soluble boron at 1490 wppm.^cH₂O/fuel-volume ratio = 1.27; multi-group ENDF/B-IV cross sections calculated $K = 0.984$ for other low-enriched uranium pin-lattice criticals at this H₂O/fuel-volume ratio.^dB&W calculates control rods to be worth 10.5% at hot, zero power.Table 12. Normal Core Shutdown With Boron at 3180 wppm^a

Case Description	Monte Carlo Code	Multiplication Factor
A. As-built, cold shutdown ^b	KENO-IV	0.737 ± 0.006
	MORSE-SGC/S	0.752 ± 0.007
B. Case A with control rods out	MORSE-SGC/S	0.805 ± 0.006
C. Case A with LBP rods removed	MORSE-SGC/S	0.778 ± 0.008
D. Case A with control rods out and LBP rods removed	MORSE-SGC/S	0.819 ± 0.007

^aValue as of July 1, 1979.^bCoolant at 293°K, $\rho = 1.0$, fuel at 293°K.

the $\text{U}_3\text{O}_8-\text{H}_2\text{O} + \text{B}$ mixture to 0.72 in the regions with ZrO_2 in the coolant to 1.07 in the remainder of the pin-lattice core. The average water-to-fuel volume ratio is 0.95.

The control rod worth for the borated core (Cases A and B) is less than 2% $\Delta k/k_1 k_2$. However, the control rod worth for the unborated core (Cases D and F) is approximately 9% $\Delta k/k_1 k_2$. Similarly, the lumped burnable poison rod worth for the borated core (Cases A and C) is less than 1% $\Delta k/k_1 k_2$, while the unborated core worth (Cases E and F) is approximately 5% $\Delta k/k_1 k_2$. Note that portions of the control and lumped burnable poison rods originally positioned in the disrupted region of the core are missing from this model.

The results from the analysis of the KENO-IV "Displaced-Fuel Slump" model are given in Table 14. Comparison of Case A with the as-built, cold shutdown case in Table 12 indicates that the positive reactivity worth of the fuel displacement is approximately 17% $\Delta k/k_1 k_2$. The average water-to-fuel volume ratio is 1.06 for this configuration. Since this value is close to that of the "Three Jump Slump" model and the positive reactivity worths are the same, it appears that the reactivity can be grossly correlated with the water-to-fuel volume ratio.

However, the differential reactivity worths of the disruptive core mechanisms are highly dependent upon the particular features of the disrupted core models. For example, removal of the soluble boron from the pin-lattice portion of the core is worth 15% $\Delta k/k_1 k_2$ for the "Three Jump Slump" model while it is worth more than 25% $\Delta k/k_1 k_2$ for the "Displaced-Fuel Model." In the latter case, the coolant channels are at normal size and the boron is worth much more. Also, the control rods are worth more

^bBoron remaining in U₃O₈-H₂O mixture.

than 3% $\Delta k/k_1k_2$ which, although small, is substantially more than the corresponding value for the "Three Jump Slump" model (<2% $\Delta k/k_1k_2$). This difference is all the more remarkable because the "Three Jump Slump" model has 73 percent more intact control rod volume than does the "Displaced-Fuel Slump" model. Evidently, the neutron moderation level has a very strong effect upon the control rod worth.

The results from the analysis of the KENO-IV "In-Place Fuel Slump" model are given in Table 15. Here we have the variation of the system multiplication factor as the fuel is displaced downward in the pins and the clad expands to accommodate the increase in cross-sectional area. The water-to-fuel volume ratio varies from 1.65 for the as-built core to 0.31 for the case with the fuel pins touching. A new reactivity search technique¹⁴ was used with these results to predict an optimum water-to-fuel volume ratio of 0.62. The maximum multiplication factor calculated in the study was 0.845 for the case in which the water-to-fuel volume ratio is 0.77. Both the system multiplication factor and the water-to-fuel volume ratio are in the range of the values calculated with the "Three Jump Slump" and the "Displaced-Fuel Models". The slightly lower water-to-fuel volume ratio corresponding to an equivalent multiplication factor with the "In-Place Fuel Slump" model is probably due to the presence of control and lumped burnable poison rods throughout this system. The fixed absorbers enhance the positive reactivity effect of spectral hardening. Indeed, the XSDRNPM lattice cell calculations do not include fixed absorbers and their results indicate a maximum system multiplication factor at a higher water-to-fuel volume ratio.

VI. CONCLUSIONS

The significant results of the parametric studies, the benchmark critical analyses and the disrupted core analyses are summarized.

Parametric Studies--Infinite fuel-pin lattice and infinite fuel-coolant media analyses indicate that, while the fuel assemblies in unborated water are undermoderated, the high soluble boron content causes the shutdown configuration to be overmoderated. Therefore, core disruptive mechanisms which remove the coolant from the core introduce positive reactivity insertions. Core disruptive mechanisms introducing positive reactivity are:

1. Fuel pin lattice-pitch reduction,
2. Fuel pin swelling,
3. ZrO₂ in coolant channels, and
4. Fuel displacement into U₃O₈-H₂O + B mixtures.

At very low water-to-fuel volume ratios (<0.6 for 2400 wppm boron, <0.4 for 3180 wppm boron), the borated systems become undermoderated and any further ejection of the coolant reduces the system multiplication factor. As a limiting case, an infinite medium of dry U(2.97)O₂ has a multiplication factor of 0.66.

Benchmark Critical Analyses--The Three Mile Island Unit 2 reactor in a critical configuration at hot, zero-power startup was analyzed as a benchmark experiment. The results of this analysis validate the analytical methods used in this study for the following reasons:

1. The multiplication factor for the benchmark configuration agreed well with the expected value drawn from the analyses of similar critical experiments using the same transport programs and the multigroup, ENDF/B-IV based, neutron cross sections.
2. Good agreement was obtained between independent analyses of the benchmark configuration using the Monte Carlo transport programs MORSE-SCG/S and KENO-IV.
3. Good agreement was obtained between calculated control rod worths and those predicted by the Babcock and Wilcox Company.
4. Good agreement was obtained between calculated lumped burnable poison rod worths and those predicted by the Babcock and Wilcox Company.

Disrupted Core Analyses--The analysis of three disrupted core models and a cold shutdown, normal-core base case yielded several important considerations.

1. Positive reactivity insertions due to the various core disruptive mechanisms increased the system multiplication factor from approximately 0.74 to 0.86.
2. To a first order approximation, the increase in reactivity for the three models can be correlated with a decrease in the borated water-to-fuel volume ratio.
3. The reactivity worths of the control rods and the lumped burnable poison rods are significantly reduced by the high soluble boron content in the reactor.
4. The presence of fixed absorbers in the disrupted portions of the core significantly reduces the reactivity worth of the soluble boron.
5. The water-to-fuel volume ratio corresponding to the maximum system multiplication factor is influenced by neutron absorption due to either fixed absorbers or the soluble boron.

APPENDIX B

MORSE-SGC/S Input Procedure

Copies of the card image input and certain input edits for the MORSE-SGC/S "Three Jump Slump" disrupted core model analysis are presented here. The primary purpose of this appendix is to provide an example of how arrays are nested using the MARS (Multiple Array System) in MORSE-SGC/S. Similar sets of input were prepared for the MORSE-SGC/S analyses of the benchmark critical configuration and the cold shutdown configuration. Of particular interest in this input procedure is the creation of fuel assemblies from combinatorial geometry input zones followed by the combination of fuel assemblies to form the reactor core. Through the MARS universe specifications, the base level or "null universe" consists of the entire system. This includes the U₃O₈-H₂O + B mixture as an input zone and the reactor core as a truncated array. In turn, this truncated array contains the fuel assembly arrays defined as universes with negative identification numbers. The various items in this procedure are indicated in the following list:

<u>Item</u>	<u>Cards</u>	<u>Page</u>
MORSE-SGC/S Control Parameters	1-6	B3
Combinatorial Geometry Bodies	9-48	B3
Combinatorial Geometry Input Zones (Note U ₃ O ₈ -cards 143, 144; RPP's 16-18, 37-40)	50-146	B4
MARS Universe Specifications	149	B5
Media Numbers	150-153	B5

<u>Item</u>	<u>Cards</u>	<u>Page</u>
Array Size Specifications (Note 15 x 15 x 7 for array 14, reactor core)	154-155	B5
13 Fuel Assembly Arrays (15 x 15 x 1)	156-187	B5
Seven 15 x 15 Arrays for Axial Levels in Core	188-279	B6
MORSE-SGC/S Starting Parameters	280	B7
Splitting and Russian Roulette Parameters	281	B7
Mixing Table for Macroscopic Constants	282-295	B7
Fission Neutron Energy Distribution	296-300	B7
MORSE-SGC/S Edit of Control Parameters		B7
Printer Plots of 13 Fuel Assembly Arrays (Each symbol denotes a pin type)		B8-B14
Printer Plots of 7 Axial Levels in Core (Each negative symbol denotes a fuel assembly array, note disrupted region in levels 5, 6, and 7)		B15-B18

APPENDIX C

KENO-IV Input Procedures

Copies of the card image input and certain input edits for the KENO-IV "Displaced-Fuel Slump" and "In-Place Fuel Slump" disrupted core modal analyses are presented here. The primary purpose of this appendix is to demonstrate the use of the MAKARAY module in preparing the mixed-box orientation array for KENO-IV. MAKARAY is a program developed to simplify the specification of KENO-IV input data for large arrays. The approach taken is to first specify subarrays, in this case fuel assemblies, and then combine the subarrays to form the mixed-box orientation array. The one-quarter core geometry shown in Fig. 4.3-1 of Appendix A is the core geometry specified here. It consists of a 120 x 120 array of pin lattice locations, water gaps between assemblies, and water peripheral to the core. It includes seven unique combinations of fuel types and fixed absorbers defining 15 x 15 unit subarrays interior to the core. Additionally, along the horizontal core midplanes there are five unique 15 x 8 subarrays, five unique 8 x 15 subarrays, and a central 8 x 8 subarray. Hemicylinders are used to specify the fuel and absorber rods located on the core midplanes. The various items appearing in the input are indicated in the following list:

<u>Item</u>	<u>Page</u>
NITAWL Input for Cross Section Processing	C3
MAKARAY Input for Core Midplane Arrays	C4
MAKARAY Input for 6 Full Assemblies (15 x 15)	C5
MAKARAY Input for Peripheral Water (15 x 15) and Water Gaps (1 x 8, 8 x 1, 1 x 15, 15 x 1, 1 x 1)	C5

<u>Item</u>	<u>Page</u>
MAKARAY Input for 7th Full Assembly (Fuel C-Box 6, LBP2-Box 8, 24th subarray specified)	C5
MAKARAY Input for Combining Subarrays	C6
KENO-IV Control Parameters Edit	C6
KENO-IV Mixing Table for Macroscopic Constants	C7
KENO-IV Box Type Specifications (Note Box 6 for Fuel C-Material 3, Box 8 for LBP2-Material 5, each with Zr Clad-Material 9)	C8-C9
NITAWL Table of Contents	C10
Printer Plots of MAKARAY Subarrays Core Midplane Arrays	C10-15
Full Assembly Arrays (15 x 15)	C16-C18
Peripheral Water (15 x 15)	C19
Water Gap (Subarrays 20, 21, 22, 23 omitted)	C19
24th Subarray for Fuel C-LBP2 (Note Box Type 6 and Box Type 8)	C20
Subarray Combination for Mixed-Box Orientation Array (Center of core is subarray 1, Note subarray 24)	C20
Portion of Mixed-Box Orientation Array (Note Fuel-C, LBP2 Assembly)	C21
KENO-IV Mixing Table for "Displaced-Fuel Slump" Model Analysis	C22
Input Stream for "In-Place Fuel Slump" Model Analysis (Note differences between this and previous case for NITAWL resonance processing data, KENO-IV mixing table, KENO-IV specifications for the fuel radius and height. The MAKARAY specifications are the same for both cases.)	C24-C30
